Introduction and Problem Formulation

▣ Wireless Sensor Network (WSN)

▣ Applications of WSN

▣ Target Detection

▣ Problem Formulation

▣ Example

Decision Fusion: Algorithms and Analysis

Performance Evaluation

Concluding remarks

- ▲ Large number of small, inexpensive, **low-power** sensors
- ▲ Can be deployed in a regular pattern (e.g. grid) or at random (“smart dust”)
- ▲ Sensors **communicate** with other sensors and remote center
- ▲ Sensors **collect information** about the surrounding environment
- ▲ Sensors have some **data processing** capabilities
- ▲ **Fusion center** processes data from sensors and makes a global (and more precise) situational assessment

# Applications of WSN

▣ Wireless Sensor Network (WSN)

▣ Applications of WSN

▣ Target Detection

▣ Problem Formulation

▣ Example

Decision Fusion: Algorithms and Analysis

---

Performance Evaluation

---

Concluding remarks

---

▲ **Environmental** monitoring (endangered species, agriculture)

▲ **Security** (surveillance, intruder detection)

## Constraints

▲ **Low power**: minimize data processing and communications costs

▲ Communication to center expensive  $\Rightarrow$  **distributed algorithms**

## Major design issues

▲ **Coverage**  $\Rightarrow$  theory of coverage processes

▲ **Connectivity**  $\Rightarrow$  random graphs theory

▲ **Localization** (use of GPS, anchor nodes)  $\Rightarrow$  MDS, etc.

▲ **Reliability**

# Target Detection

- ▣ Target Detection
- ▣ Problem Formulation
- ▣ Example

## Decision Fusion: Algorithms and Analysis

---

## Performance Evaluation

---

## Concluding remarks

---

- ▲ Detect and characterize targets in the monitored area
- ▲ Assume **communication issues are resolved** separately (connectivity, transmission protocols, etc)
- ▲ Assume **sensor locations are known** or can be estimated accurately
- ▲ Here focus on **detection of a single target**

# Problem Formulation

Introduction and Problem Formulation

- Wireless Sensor Network (WSN)
- Applications of WSN
- Target Detection
- Problem Formulation**
- Example

Decision Fusion: Algorithms and Analysis

Performance Evaluation

Concluding remarks

- ▲ N sensors deployed over monitored region R (WLOG unit square)
- ▲ A target at location  $v$  emits signal with amplitude  $S_0$
- ▲ Sensor  $i$  located at  $s_i$  gets **energy** readings

$$E_i = S_i + \epsilon_i = S_0 c(\|v - s_i\|, \eta) + \epsilon_i,$$

where  $c(\cdot)$  is a monotone signal decay function

- ▲  $\epsilon_i$  is **random noise**; assume  $\epsilon_i$  are i.i.d.
- ▲ Each sensor makes a **decision**

$$d_i = \mathbf{1}(E_i \geq \tau)$$

- ▲ The sensor's **false alarm probability**  $\alpha$  is assumed known (prior information on noise or hardware);  $v, S_0, \eta$  unknown

# Example: exponentially decaying signal model

$$S_i(v) = S_0 \exp(-\|s_i - v\|^2 / \eta^2), \quad \epsilon_i \sim \mathcal{N}(0, \sigma^2)$$

▣ Local Vote Decision Fusion (LVDF)

▣ ODF vs LVDF

▣ LVDF: threshold selection

▣ A normal approximation for the false alarm

▣ Calculating Covariance

▣ Comments on the approximation

Performance Evaluation

Concluding remarks

▲ Only positive decisions  $d_i$  are transmitted to fusion center

▲ Low communication cost

▲ More robust to noise

**Ordinary Decision Fusion (ODF):**

Fusion center makes the final decision  $\mathbf{1}(\sum_{i=1}^N d_i \geq T)$

▲ Key issue: must choose  $T$  to control system-wide false alarm  $F$

▲ Decisions  $d_i$  are i.i.d., so

$$F = \sum_{i=T}^N \binom{N}{i} \alpha^i (1 - \alpha)^{N-i} \approx 1 - \Phi \left( \frac{T - N\alpha}{\sqrt{N\alpha(1 - \alpha)}} \right)$$

▷ A normal approximation for the false alarm

▷ Calculating Covariance

▷ Comments on the approximation

Performance Evaluation

Concluding remarks

**Early decision fusion algorithms:** radar array applications

- ▲ Studied replacing  $\sum_{i=1}^N d_i$  with  $\sum_{i=1}^N w_i d_i$
- ▲ **Classical decision theory** can be applied if false alarm and detection probabilities are known for all sensors - unrealistic for WSN

**Modern algorithms** for WSN:

- ▲ ad hoc modifications of  $d_i$  by various “quality” measures (e.g., level of neighborhood agreement) **improve detection**
- ▲ **no performance guarantees** (cannot choose  $T$  to guarantee  $F$ )

Performance Evaluation

Concluding remarks

1. Sensor  $i$  makes an initial decision  $d_i$  and communicates it to all sensors in its neighborhood  $U(i)$ .
2. Given the set of decisions  $\{d_j : j \in U(i)\}$ , sensor  $i$  adjusts its initial decision according to a **majority vote**:

$$Z_i = \mathbf{1}\left(\sum_{j \in U(i)} d_j > M_i/2\right),$$

where  $M_i = |U(i)|$  is the size of the neighborhood.

3. The fusion center makes the final decision

$$\mathbf{1}\left(\sum_{i=1}^N Z_i \geq T_\ell\right).$$

In practice, sensors only transmit positive decisions in steps 1 and 3.

Performance Evaluation

---

Concluding remarks

---

Goal: a **central limit theorem** for the modified decisions  $Z_i$

- ▲  $Z_i$  are binary, non-identically distributed, and **weakly dependent**
- ▲ **Regular grids**: adapted from CLT for non-stationary  $\alpha$ -mixing random fields (Guyon, 1995).
- ▲ **Random deployment**: adapted from CLT for functionals of marked Poisson and binomial point processes (Penrose & Yukich, 2001, 2002).
- ▲ Some care needed in taking limits as  $N \rightarrow \infty$ , region  $R$  remains fixed.

- Local Vote Decision Fusion (LVDF)
- ODF vs LVDF
- LVDF: threshold selection
- A normal approximation for the false alarm**
- Calculating Covariance
- Comments on the approximation

Performance Evaluation

Concluding remarks

Let  $n_{ij} = |U(i) \cap U(j)|$ .  $Z_i$  and  $Z_j$  are dependent iff  $n_{ij} > 0$ .

$$F = P\left(\sum_{i=1}^N Z_i \geq T_\ell\right) \approx 1 - \Phi\left(\frac{T_\ell - \sum_{i=1}^N \mu_i}{\sqrt{\sum_{i=1}^N \sigma_i^2 + \sum_{i \neq j, n_{ij} > 0} \text{Cov}(Z_i, Z_j)}}\right).$$

• Mean and variance are easy (binomial):

$$\mu_i = E(Z_i) = P(Z_i = 1) = \sum_{k=[M_i/2]+1}^{M_i} \binom{M_i}{k} \alpha^k (1 - \alpha)^{M_i - k},$$

$$\sigma_i^2 = \text{Var}(Z_i) = \mu_i(1 - \mu_i),$$

- Local Vote Decision Fusion (LVDF)
- ODF vs LVDF
- LVDF: threshold selection
- A normal approximation for the false alarm
- Calculating Covariance**
- Comments on the approximation

Performance Evaluation

Concluding remarks

$A$ : # positives in  $U(i) - U(j)$

$B$ : # positives in  $U(i) \cap U(j)$

$C$ : # positives in  $U(j) - U(i)$

$A, B, C$  are independent binomial random variables. Condition on  $B$ :

$$E(Z_i Z_j) = \sum_{k=0}^{n_{ij}} P(B = k) P(A > \frac{M_i}{2} - k) P(C > \frac{M_j}{2} - k).$$

Performance Evaluation

---

Concluding remarks

---

- ▲ **Quite accurate** even for moderate  $N$ ; worsens as  $M$  gets larger
- ▲ **Simplifies** significantly for **regular grids**
- ▲ For random deployments, depends on locations but
  - depends on locations only through the distribution of  $M_i$ ,  $n_{ij}$
  - error essentially the same if approximation is computed from one arbitrary deployment of  $N$  sensors
  - hence **localization can be avoided**

Concluding remarks

---

The signal model is

$$S_i = S_0 \exp(-\|s_i - v\|^2/\eta^2), \quad \epsilon_i \sim \mathcal{N}(0, \sigma^2)$$

Same pattern for

- ▲ regular grids and random deployments
- ▲ distance-based and nearest neighbors based neighborhoods
- ▲ a range of  $N, \alpha, F, \eta, \text{SNR}=S_0/\sigma$ .

- ▣ Probability of detection as a function of SNR
- ▣ Probability of detection as a function of false alarm (ROC)
- ▣ Choosing the size of the neighborhood
- ▣ Sequential Decision Fusion (SDF)
- ▣ Performance evaluation for SDF

Concluding remarks

- ▲ Decisions collected **over time**  $t = 0, 1, \dots$ ; **target moves slowly** relative to the rate of time sampling
- ▲ Fusion center stores corrected LVDF decisions  $Z_i^t$
- ▲ Propose new decision algorithm: exponential moving average

$$Y_i^0 = Z_i^0,$$
$$Y_i^t = \lambda Z_i^t + (1 - \lambda) Y_i^{t-1}, \quad t = 1, 2, \dots$$

- ▲ Networks decision at time  $t$  is  $\mathbf{1} \left( \sum_{i=1}^N Y_i^t \geq \tilde{T}_\ell \right)$ .
- ▲ If noise is i.i.d. over time,

$$\tilde{T}_\ell = \sqrt{\frac{\lambda}{2 - \lambda}} T_\ell$$

- ▲ Robust to moderate temporal correlations

▶ Concluding remarks

## Local Vote Decision Fusion

- ▲ increases detection probability and works well at low SNR
- ▲ particularly large gains for well-localized signals
- ▲ saves energy (fewer false positives sent to the fusion center)
- ▲ theoretical guarantees for the system false alarm

## Other interesting problems (in progress)

- ▲ Target localization
- ▲ Estimation of target and environment parameters
- ▲ Tracking a target over time
- ▲ Multiple targets (detection and classification)
